Combined aortic and inferior vena cava injury

Basem Marcos, Yomayra Perez, Jennifer Matarlo, Jay A Yelon, Valerie Katz, Robert V Madlinger

ABSTRACT

Introduction: Combined injuries to the aorta and inferior vena cava are among the most severe traumatic injuries where mortality rates can approach 100%. Case Report: A 26-year-old male presented with multiple small caliber gunshot wounds to the right upper and lower back, right posterior arm and right gluteal area. He was diagnosed with large retroperitoneal hematoma on computed tomography (CT) scan. He underwent an exploratory laparotomy with exploration of a zone 1 retroperitoneal hematoma. An injury to the inferior vena cava (IVC) at the level of the left renal vein was identified and repaired by lateral venorraphy. Massive transfusion protocol (MTP) was activated. The patient was returned back to the operating room few hours later for recurrent bleeding. Aortic injury was identified one centimeter distal to the renal arteries secondary to ruptured pseudoaneurysm. The left renal vein was ligated for exposure. The aortic injury was repaired. The patient was resuscitated postoperatively and was discharged home without major morbidity. Conclusion: Combined inferior vena cava and infrarenal aortic injury carries a mortality of around 73%. All zone 1 retroperitoneal hematomas should be explored, with the exception of venous hematomas of the juxtahepatic vena cava. Mattox maneuver is the ideal exposure for a supramesocolic retroperitoneal hematoma and Cattell–Brash maneuver is used for inframesocolic retroperitoneal hematomas. Zone 1 retroperitoneal hematoma resulting from combined injuries to the inferior vena cava and aorta is highly lethal. Successful management requires early MTP, rapid and aggressive surgical management and application of elective vascular surgery techniques.

Keywords: Inferior vena cava injury, Aorta injury

INTRODUCTION

Combined injuries to the aorta and inferior vena cava (IVC) are among the most severe traumatic injuries and are associated with high mortality rates. Mortality rates for such injuries can approach 100%. Adherence to
advanced trauma life support protocol, principles of damage control surgery, and implementation of an evidence based massive transfusion protocol (MTP) may lead to improved survival with a decrease in major morbidity.

CASE REPORT

A 26-year-old male was brought to the emergency department (ED) by emergency medical services after he was found with multiple small caliber gunshot wounds to the right upper and lower back, right posterior arm and right gluteal area (Figure 1). On arrival his vital signs were: heart rate 72/min, respiratory rate 22/min, blood pressure 100/48 mmHg and spO2 100%. He complained of abdominal pain. On physical examination the abdomen was soft, non-distended and moderately tender over the mid-abdomen without rebound, rigidity, or guarding. Bowel sounds were present. Focused abdominal sonography for trauma (FAST) was performed in the ED which did not reveal any free fluid. Further diagnostic studies included a computed tomography (CT) scan of the abdomen and pelvis was suspicious for injuries to the abdominal aorta and portal vein.

The patient was immediately taken for operation. The MTP was activated in preparation for the possibility of a major abdominal vascular injury. Massive transfusion protocol in our institution is constituted of pRBCs:FFPs in 1:1 ratio followed by giving single donor platelets and 10 units of cryoprecipitate after 10 units each of pRBCs and FFPs. The patient underwent an exploratory laparotomy with exploration of a zone 1 retroperitoneal hematoma (Figure 2). An injury to the IVC at the level of the left renal vein was identified and repaired by lateral venorrhaphy. No bleeding was noted from the portal vein or the aorta. Hemorrhage was controlled, the abdomen was packed and left open because of mid-gut edema and the patient was transferred to the surgical intensive care unit (SICU) for continued resuscitation. A few hours later, the patient developed signs of hypovolemic shock and was immediately returned to the operating room. The MTP was again activated. Supraceliac aortic control was obtained and an aortic injury was identified one centimeter distal to the renal arteries (this was the pseudoaneurysm that was present on the initial imaging and missed during the first laparotomy and progressed to subsequent rupture). The left renal vein was ligated and divided to provide adequate exposure of the injury. The aortic injury was repaired by primary suture closure. The patient received a total of 53 units of packed red blood cells, 49 units of fresh frozen plasma, 7 units of single donor platelets, and 40 units of cryoprecipitate perioperatively. At the end of surgery, the patient’s lactate was 9.5 mmol/L and his base deficit was 18. Resuscitation was continued and these findings of hypoperfusion were corrected in less than 24 hours.

The patient underwent a planned re-exploration and abdominal washout with partial fascial closure on postoperative day (POD)-3. The abdomen was closed on POD-7. The patient developed acute cholecystitis and underwent an open cholecystectomy on POD-11. A tracheostomy was performed on POD-14. The patient spent 23 days in the SICU, four days in the surgical ward and he was then transferred to an acute inpatient rehabilitation center. The patient was seen in the surgery clinic following his discharge from inpatient rehabilitation. He was ambulating and tolerating a diet. His tracheostomy had been removed and the site of his tracheostomy.

DISCUSSION

The retroperitoneum is divided to zone 1 (around the abdominal aorta and IVC), zone 2 (around both the kidneys), and zone 3 (in the pelvis). Zone 1 retroperitoneal hematoma is a sign of a major abdominal vascular injury. Penetrating trauma accounts for approximately 90% cases. The overall mortality rate is 57%. Mortality rates range from 30% for an infrarenal IVC injury, 50% for an infrarenal aortic injury, 60% for an injury to the suprarenal abdominal aorta and 100% for combined injuries to the suprarenal abdominal aorta and IVC. Our patient had an injury to the IVC as well as an infrarenal aortic injury, which carries approximately 73% mortality rate. Factors associated with increased
mortality are presence of shock at the time of admission, bleeding without retroperitoneal tamponade, acidosis, and suprarenal injury [1].

This injury is more common in urban trauma centers than it is in military conflicts. Debakey et al. reviewed 2,471 patients with arterial injuries during World War II. Two percent patients had abdominal arterial injuries. Rich et al. reviewed 1,000 patients with arterial injuries sustained in the Vietnam War. Only 2.9% injuries involved abdominal vessels. A thirty-year review of 5,760 cardiovascular injuries seen at Ben Taub Hospital (Houston, TX, USA) found that 33.8% patients had abdominal vascular injuries. This difference is thought to be due to the increased wounding power of military weapons, delayed transport and torso body armor [2].

Patients can present clinically with one of two pictures: (i) contained hematoma with transient hypotension responding to crystalloid boluses, or (ii) free intraperitoneal rupture with marked hypotension which does not respond to fluid boluses. Patients with contained hematoma, like our patient, can remain hemodynamically normal until the hematoma is opened in the operating room. In one review, patients with a contained hematoma had a mean base deficit of 7.2, mean transfusion of 8.6 units of blood, and a survival rate of 96%. Those with free intraperitoneal rupture had a mean base deficit of 14.7, mean transfusion of 15.1 units and 43% survival [2]. In patients with penetrating abdominal trauma to the back and flank who are hemodynamically normal, CT scan of the abdomen can be obtained for further evaluation of injuries prior to surgery [3].

In cases with penetrating abdominal trauma, standard trauma principles apply. These include exploration via a midline incision, four quadrant packing and evacuation of blood and blood clots. Proximal and distal vascular control is essential and can be achieved by a variety of vascular techniques, including direct digital pressure, pressure with laparotomy pads (packing) or pressure with sponge sticks. Enteric injuries are addressed with clamps or staples. An associated ureteral injury may be treated initially by ligating the ureter during damage control surgery.

All zone 1 retroperitoneal hematomas should be explored, with the exception of venous hematomas of the juxtahepatic vena cava [4]. A left medial visceral rotation (Mattox maneuver) is the ideal exposure for a supramesocolic retroperitoneal hematoma and the right medial visceral rotation or Cattell–Brash maneuver with Kocherization of the duodenum is used for inframesocolic retroperitoneal hematomas [5].

After hemorrhage control of the injured aorta or IVC is obtained, exploration of the hematoma is begun at the highest point. Lateral repair (simple primary suture repair) of the aorta and IVC should be attempted. Complex vascular repairs can be performed if there is loss of part of the arterial wall, but this is time consuming. The left renal vein can be ligated and divided. This aids in exposure of injuries at this level. If IVC repair is not possible, the IVC can be ligated. Lower extremity fasciotomies may be needed along with aggressive resuscitation. The infrarenal aorta can be ligated if it cannot be repaired with axillary bifemoral extra-anatomic bypass performed later, if the patient survives [4].

CONCLUSION

Zone 1 retroperitoneal hematoma resulting from combined injuries to the inferior vena cava and aorta is highly lethal. Management should be individualized based on the patient’s presentation. Key maneuvers are hemorrhage control and exposure. Successful management of acute traumatic injury to both the abdominal aorta and inferior vena cava requires early activation of massive transfusion protocol, rapid and aggressive surgical management, including damage control techniques and application of techniques and principles developed for elective vascular surgery.
