Granular cell tumor of the hand: A case report

Daniela Fanto, Salvatore Fanto

ABSTRACT

Introduction: Granular cell tumors are rare soft tissue neoplasms of presumed neural origin. The lesions tend to be small and solitary, asymptomatic, and typically found in the dermis or subcutaneous tissue. They have rarely been reported as occurring in the hand. Complete excision is usually curative. However, malignant tumors have been reported, which may metastasize.

Case Report: We report a case of a granular cell tumor of the hand.

Conclusion: This case is of particular interest due to the atypical location, and clinical presentation, which despite its malignant potential, mimics that of more commonly encountered benign lesions such as ganglion cysts and inclusion cysts.

INTRODUCTION

Granular cell tumor (GCT) is a rare soft tissue neoplasm of presumed neuroectodermal origin [1, 2]. The majority are benign, and a malignant variant accounts for only 1–3% of cases [3, 4]. In a large series by Lack et al. of 110 patients diagnosed with GCT, none were found to be malignant. Granular cell tumor is usually located in the head and neck with hand and peripheral nerve lesions being distinctly uncommon [3]. Lesions are most commonly found in the dermis or subcutaneous tissue, thus mimicking adnexal tumors. Demographically, GCT more commonly affects females in their 40s or 50s of African-American origin [5]. However, in the Lack et al. series, reported incidence was 35% in females and 65% in males [6].

The lesion is usually asymptomatic, slow growing, solitary and measuring less than 3 cm [4, 7]. Due to this non-specific presentation, GCT is rarely clinically suspected prior to biopsy or surgical excision [6]. Hallmark features, although not pathognomonic of malignancy, include larger size, intramuscular location, invasion of adjacent structures and rapid growth [6, 8].

The case outlined is of particular interest as it presented as a more commonly encountered benign dermal subcutaneous lesion. As GCTs do have a potential for malignancy and for metastases, this tumor should be kept in mind as a differential diagnosis.

CASE REPORT

A 48-year-old African-American female presented with a nodule on the dorsum of her right hand, which she first noticed a few months earlier. She reported that the nodule had been slowly increasing in size. Physical examination revealed a hard non-tender round nodule approximately 1.5 cm in diameter overlying the extensor tendons of the index and long fingers. The lesion was located in the subcutaneous plane dorsal to the extensor tendons without infiltration of surrounding structures. The excision of nodule was performed under local anesthesia (Figure 1).
Pathology revealed a granular cell tumor, specifically the lesion consisted of a population of relatively large polyhedral cells with finely granular cytoplasm due to high mitochondrial content and small, dense and central nucleus (Figures 2–4). The lesion had a cellular center with a peripheral infiltrating pattern, splitting the adjacent collagen fibers, with ill-defined borders. There was mild atypia in focal areas with no cellular pleomorphism, mitotic activity, or necrosis (Figures 2–4). Immunohistochemically, the cells stained with S100 and CD56 and cytoplasmic staining was PAS positive as well. Follow-up at third year revealed that the patient remained symptom free and without any signs of recurrence.

**DISCUSSION**

Abrikossoff first described GCT in 1926. The lesion was located in the tongue and was thought to arise from muscle. Consequently, the neoplasm was referred to as granular cell myoblastoma [9]. Fust and Cyter [10, 11] postulated that non-lingual lesions originated from peripheral nerves and coined the term granular cell...
Granular cell tumor is commonly found in the dermis or subcutaneous tissue with intramuscular lesions being uncommon [4, 10]. The tumor has been documented in various sites in the body. However, the head and neck areas appear to be most commonly affected. Hand lesions are rare. In a large series involving 95 patients, Strong et al. reported that most lesions were located in the head and neck area, with only seven involving the fingers and two palms [3]. Lack et al. reported on 110 patients during a 32-year period, and found that 38 tumors arose from the oral mucosa, and 48 from the skin and subcutaneous tissue, most commonly the trunk and upper extremities [6]. Differential diagnoses for such lesions include the more commonly encountered ganglion cysts, inclusion cysts, fibromas and neuromas.

Preoperative workup varies depending on the history and the clinical findings. In some cases, X-ray and MRI scan have been used. Typically, MRI scan is most useful for the preoperative workup of larger lesions for both diagnostic purposes and preoperative planning. MRI findings indicative of GCT include heterogeneous low signal intensity on T1-weighted images and a central low signal with peripheral high signal on T2-weighted images with some lesions being darker on T1-weighted and T2-weighted images than fat [8]. Although these findings may be helpful during diagnostic workup such features are not specific or sufficient in establishing a definitive diagnosis.

Further management includes FNA and wide excision, the latter being the favored and most definitive therapy. Histologically, the tumors demonstrate polygonal sheaths of cells with distinct borders, eosinophilic granular cytoplasm and a small central nucleus [6, 8]. Cytoplasmic granules are PAS+ and diastase resistant [6]. Immunohistochemical staining is typically positive for S100 protein, neuron specific enolase, laminin and various myelin proteins [12]. S100 protein positivity is indicative of neural derivation, as this protein is associated with neural ectodermal cells. Histological differential diagnoses may include but are not limited to renal cell carcinoma, granuloma, alveolar soft part sarcoma and hibernoma. Histopathological diagnostic criteria for malignancy have been studied by Fanburg-Smith et al., who reported that most lesions were located in the head and neck area, with only seven involving the fingers and two palms [3]. Lack et al. reported on 110 patients during a 32-year period, and found that 38 tumors arose from the oral mucosa, and 48 from the skin and subcutaneous tissue, most commonly the trunk and upper extremities [6]. Differential diagnoses for such lesions include the more commonly encountered ganglion cysts, inclusion cysts, fibromas and neuromas.

Further management includes FNA and wide excision, the latter being the favored and most definitive therapy. Histologically, the tumors demonstrate polygonal sheaths of cells with distinct borders, eosinophilic granular cytoplasm and a small central nucleus [6, 8]. Cytoplasmic granules are PAS+ and diastase resistant [6]. Immunohistochemical staining is typically positive for S100 protein, neuron specific enolase, laminin and various myelin proteins [12]. S100 protein positivity is indicative of neural derivation, as this protein is associated with neural ectodermal cells. Histological differential diagnoses may include but are not limited to renal cell carcinoma, granuloma, alveolar soft part sarcoma and hibernoma. Histopathological diagnostic criteria for malignancy have been studied by Fanburg-Smith et al., who reported a case series of 73 patients with malignant soft tissue GCT. We conclude that the presence of three or more of the following histologic criteria confirms the diagnosis of a malignant lesion: necrosis, spindling, vesicular nuclei with large nucleoli, increased mitotic activity (>2 mitoses/10 high-power fields at x200 magnification), high nuclear to cytoplasmic (N:C) ratio, and pleomorphism [13]. A further adverse prognostic factor in terms of survival is a Ki67 proliferation index less than 10% [13].

Recurrence of benign GCTs following wide excision is rare and most likely associated with incomplete resection [6]. Lack et al. reported an 8% recurrence rate in patients diagnosed with GCT who were treated surgically, and in each case, one or more the surgical margins of resection had tumor involvement [6]. Adequate follow-up is imperative as malignant lesions can recur and may metastasize, making these the most definitive features of malignancy [14].

Given that we do not currently know the possible mechanism of malignant transformation, close follow-up is essential.

CONCLUSION

It is important to be aware that granular cell tumor presentation typically mimics that of commonly occurring benign lesions, such as ganglion cysts and fibromas. Although granular cell tumors are rare, it is important to consider the possibility of this potentially malignant diagnosis.

Edorium Journals: An introduction

Edorium Journals Team

About Edorium Journals
Edorium Journals is a publisher of high-quality, open access, international scholarly journals covering subjects in basic sciences and clinical specialties and subspecialties.

Our Commitment

Six weeks
You will get first decision on your manuscript within six weeks (42 days) of submission. If we fail to honor this by even one day, we will publish your manuscript free of charge.

Four weeks
After we receive page proofs, your manuscript will be published in the journal within four weeks (31 days). If we fail to honor this by even one day, we will publish your manuscript free of charge and refund you the full article publication charges you paid for your manuscript.

Vision of being the best
We have the vision of making our journals the best and the most authoritative journals in their respective specialties. We are working towards this goal every day of every week of every month of every year.

Exceptional services
We care for you, your work and your time. Our efficient, personalized and courteous services are a testimony to this.

Editorial Review
All manuscripts submitted to Edorium Journals undergo pre-processing review, first editorial review, peer review, second editorial review and finally third editorial review.

Peer Review
All manuscripts submitted to Edorium Journals undergo anonymous, double-blind, external peer review.

Early View version
Early View version of your manuscript will be published in the journal within 72 hours of final acceptance.

Manuscript status
From submission to publication of your article you will get regular updates (minimum six times) about status of your manuscripts directly in your email.

Invitation for article submission
We sincerely invite you to submit your valuable research for publication to Edorium Journals.

But why should you publish with Edorium Journals?
In less than 10 words - we give you what no one does.

Mentored Review Articles (MRA)
Our academic program “Mentored Review Article” (MRA) gives you a unique opportunity to publish papers under mentorship of international faculty. These articles are published free of charges.

Favored Author program
One email is all it takes to become our favored author. You will not only get fee waivers but also get information and insights about scholarly publishing.

Institutional Membership program
Join our Institutional Memberships program and help scholars from your institute make their research accessible to all and save thousands of dollars in fees make their research accessible to all.

Our presence
We have some of the best designed publication formats. Our websites are very user friendly and enable you to do your work very easily with no hassle.

Something more...
We request you to have a look at our website to know more about us and our services.

We welcome you to interact with us, share with us, join us and of course publish with us.
