ABSTRACT

Introduction
Obscure Gastrointestinal Bleeding (OGIB) represents about 5% of all GI bleeds. This can pose a huge diagnostic challenge for clinicians. Small Bowel Angiodysplasia is a rare but important cause of OGIB that is difficult to diagnose and treat.

Case Report
We present the case of a 53-year-old lady with a 1-month history of malaena and symptomatic anaemia who presented to general hospitals in Yangon, Myanmar. After multiple investigations, she was diagnosed with Jejunal Angiodysplasia. We highlight the challenges that come with diagnosing and managing a rare but important cause of upper GI bleeding, made even more difficult in a resource-limited setting where healthcare is not always affordable and accessible.

Conclusion
Small Bowel Angiodysplasia should be on the differential list for all patients who present with OGIB or any GI bleeding. Early diagnosis is important so that appropriate treatment can be administered for this potentially life-threatening condition.

Keywords: jejunal angiodysplasia, obscure gastrointestinal bleeding
INTRODUCTION
Angiodysplasia is a type of vascular malformation with fragile and leaky vessels that can affect anywhere along the GI tract. It is responsible for about 6% of lower GI bleeding and between 1.2 to 8% of upper GI bleeding [1]. Obscure Gastrointestinal Bleeding (OGIB) represents about 5% of all GI bleeds [2], with Small Bowel Angiodysplasia estimated to account for around 30 to 40% of cases [3]. Thus, it is an important differential that must be considered. Clinically, its presentation can vary from being an incidental finding to OGIB or chronic anaemia. These patients should be evaluated with oesophagastroduodenoscopy (OGD), colonoscopy, video capsule endoscopy (VCE) and angiography. Additionally, a red blood cell scan can increase the sensitivity of diagnosis when used in combination with angiography [4][5]. In acute presentations, endoscopic therapy should be used to treat active bleeding from angiodysplasia. Options include argon plasma coagulation (APC), sclerosant injections and gel foam embolisation. Double Balloon Enteroscopy (DBE) can be used for both diagnostic and therapeutic purposes. For long term management, somatostatin analogues, hormonal therapy or anti-angiogenics can be used [6]. In refractory bleeding or if lesions are at inaccessible sites, surgical localisation and resection of the diseased segment can be performed.

CASE REPORT
A 53-year-old lady presented to Thingangyun Sanpya General Hospital, Yangon, Myanmar in February 2017 with a 1-month history of increasing dyspnoea, palpitations and pallor. She recalled a few episodes of malaena. There were no other cardiac, respiratory or gastrointestinal symptoms. Apart from severe conjunctival pallor, physical examination and digital rectal examination were unremarkable. Blood tests revealed a hypochromic microcytic anaemia (Hb 5.3, MCV 53.4) and she was found to have HbE trait on haemoglobin electrophoresis. She was transfused 5 units of blood. An OGD performed showed a duodenal ulcer and gastric vascular ectasia which was subsequently treated with argon plasma coagulation (APC). However, these findings could not explain her severe anaemia and a colonoscopy was later performed in March 2017. The colonoscopy revealed small polyps in the descending and sigmoid colon which were tubular adenomas on histology. These findings still
could not explain her severe anaemia. A month later, VCE was performed to locate potential sources of bleeding. This showed active small bowel bleeding in the last part of the duodenum and jejunum (Figure 1). An ultraslim colonoscope was then used to better visualise the small bowel, showing multiple angiodysplastic spots with active bleeding in the proximal jejunum. APC was applied and a diagnosis of Jejunal Angiodysplasia was made (Figure 2).

The patient presented again, this time to Yangon General Hospital, Yangon, Myanmar towards the end of April 2017 with similar worsening anaemic symptoms (Hb 3.5). She was transfused 4 units of blood, stabilised and discharged. A CT angiogram (mesenteric angiogram) was performed in May 2017. The result showed contrast-enhancing wall thickening at the second part of the duodenum, but no serpiginous vascular channels or contrast extravasation was observed. Due to the equivocal results, a slim colonoscope was used to visualise the jejunum again, and this was normal up to the duodenal-jejunal junction. The patient was transfused 2 units of blood, discharged and followed up in clinic, with a plan for a DBE if symptomatic anaemia recurred.

DISCUSSION

Small Bowel Angiodysplasia is a rare but important cause of OGIB or upper GI bleeding. It should be considered in the differential list for GI bleeding and chronic anaemia, especially in patients with negative OGD and colonoscopies [3]. In this case, multiple GI pathologies were initially discovered in this patient on OGD and colonoscopy. Sound clinical judgment was required to deduce that the findings could not explain the patient’s clinical presentation, hence further investigations were undertaken. In all, there was a 4-month time period between symptom onset and final diagnosis. Small Bowel Angiodysplasia is a challenging condition to formally diagnose; VCE and CT angiography play a key role, and these should be requested in patients with negative GI scope procedures, or with results that do not correlate with clinical presentation.

In this case, however, CT angiography results were equivocal for angiodysplasia. This could be because the patient was not actively bleeding at the time of investigation. Additionally, radiologists recommended that the "GI haemorrhage CT
angiogram protocol" should have been specifically requested according to local hospital guidelines. This should be stated on the request form to prompt radiologists to focus particularly on GI mucosal vessels. A multidisciplinary team meeting was later conducted, with the team concluding that there was enough evidence for a formal diagnosis of Jejunal Angiodysplasia to be made despite the equivocal angiogram. This is a rare condition not commonly encountered by healthcare professionals, hence many were unfamiliar with diagnostic methods. A multidisciplinary team approach involving gastroenterologists, general surgeons and emergency physicians must be adopted early to ensure quick diagnosis and management of this potentially life-threatening condition.

In terms of treatment, our patient was mainly managed supportively with blood transfusions when indicated. Endoscopic intervention via APC was only performed once. However, the patient's symptoms recurred over 4 months. Long term therapies such as octreotide could be considered in this case, and further surgical intervention should symptoms continue to persist.

Many problems exist in the field of healthcare in Myanmar, including poor access to hospitals and a shortage of resources and health professionals [7]. There are a total of only 5 public endoscopy centres in the entire country and a shortage of gastroenterologists, which is insufficient for a population of over 51 million people. Private facilities are available, but many people live in poverty, and they are often unable to afford these services. In this case, the delay from presentation to diagnosis could be explained by the challenging nature of the illness, and also the difficulty in accessing relevant investigations more quickly. Doctors in resource-limited settings like these are forced to rely more on their clinical judgment in making diagnoses. They must also be more familiar with local hospital protocols and stay up to date with their knowledge given the lack of national guidelines and rare presentation of this case.

CONCLUSION

In conclusion, Small Bowel Angiodysplasia is a rare but important cause of OGIB. It should be on the differential list for patients presenting with any GI bleeding. There should be a higher suspicion for Small Bowel Angiodysplasia if OGD and
colonoscopy yield inconclusive results. VCE and CT Angiography are useful investigations for its diagnosis. In the acute setting, management options include supportive blood transfusions and interventional endoscopy. DBE is a useful tool that can be considered for both diagnostic and therapeutic purposes. In resource-limited settings, it is important for doctors to be familiar with this condition and the diagnostic and management options available.

Learning Points
- Small Bowel Angiodysplasia is a rare but important cause of occult GI bleeding. It should be on the differential list for patients presenting with an occult GI bleed, and especially in those with inconclusive endoscopy results.
- Video Capsule Endoscopy and CT Angiography are useful investigations for diagnosing Small Bowel Angiodysplasia
- In the acute setting, management of Small Bowel Angiodysplasia include supportive blood transfusions and interventional endoscopy.
